(60) Provisional application No. 62/234,226, filed on Sep. 29, 2015, provisional application No. 62/113,511, filed on Feb. 8, 2015.

A high-speed transportation system, the system having at least one enclosed volume that is configured to be maintained as a low-pressure environment, at least one track along a transportation path within the at least enclosed volume; and a plurality of capsules configured for travel through the at least one enclosed volume between stations. The at least one enclosed volume is at least partially defined by at least one flexible material structured and arranged to withstand a tensile load.

## LOW-PRESSURE ENVIRONMENT STRUCTURES

### CROSS REFERENCE TO RELATED APPLICATIONS

[0001] The present application claims the benefit of U.S. Provisional Application No. 62/113,511 filed on Feb. 8, 2015, and U.S. Provisional Application No. 62/234,226 filed on Sep. 29, 2015, the disclosures of which are expressly incorporated by reference herein in their entireties.

### FIELD OF THE DISCLOSURE

[0002] The present disclosure relates to low-pressure environment structures for a high-speed transportation system, and methods of use thereof.

### BACKGROUND OF THE DISCLOSURE

[0003] Traditional transportation modes via water, land, rail and air revolutionized the movement and growth of our current culture. Adverse environmental, societal, and economic impacts of these traditional transportation models, however, initiated a movement to find alternative transportation modes that take advantage of the significant improvements in transportation technology and efficiently move people and materials between locations. High-speed transportation systems utilizing rails or other structural guidance components have been contemplated as a solution to existing transportation challenges while improving safety, decreasing the environmental impact of traditional transportation modes and reducing the overall time commuting between major metropolitan communities.

[0004] A high speed, high efficiency transportation system utilizes a low-pressure environment in order to reduce drag on a vehicle at high operating speeds, thus providing the dual benefit of allowing greater speed potential and lowering the energy costs associated with overcoming drag forces. In embodiments, these systems may use a near vacuum (e.g., low-pressure) environment within a tubular structure.

[0005] Tube structures for low-pressure environments, however, may have some drawbacks, including material and manufacturing costs. Thus, there exists a need for alternative structures to the tube for low-pressure environments.

### SUMMARY OF THE EMBODIMENTS OF THE DISCLOSURE

[0006] Aspects of the present disclosure are directed to a high-speed transportation system, the system comprising at least one enclosed volume that is configured to be maintained as a low-pressure environment, at least one track along a transportation path within the at least enclosed volume, and a plurality of capsules configured for travel through the at least one enclosed volume between stations. The at least one enclosed volume is at least partially defined by at least one flexible material structured and arranged to withstand a tensile load.

[0007] In embodiments, the high-speed transportation system further comprises at least one support structure configured to support the flexible material and structured and arranged to withstand a compressive load.

[0008] In further embodiments, the system additionally comprises at least one track support platform.

[0009] In additional embodiments, the at least one flexible material together with the at least one track support platform defines the at least one enclosed volume.

[0010] In some embodiments, the flexible material defines the at least one enclosed volume.

[0011] In certain embodiments, the at least one support structure comprises at least one vertical support.

[0012] In further embodiments, the at least one flexible material together with the at least one vertical support defines the at least one enclosed volume.

[0013] In additional embodiments, the at least one support structure comprises a plurality of support structures spaced along the transportation path.

[0014] In some embodiments, the at least one support structure comprises at least one angled support.

[0015] In certain embodiments, the at least one angled support is attached to a track support platform.

[0016] In further embodiments, the at least one angled support is attached to at least one vertical support.

[0017] In additional embodiments, the at least one angled support extends in a downwardly direction.

[0018] In some embodiments, the at least one angled support extends in an upwardly direction.

[0019] In certain embodiments, the at least one support structure comprises an arch structure.

[0020] In further embodiments, the high-speed transportation system further comprises a second flexible material structured and arranged to define a second enclosed volume that encloses the first enclosed volume, and which is configured to be maintained at a pressure higher than a pressure outside of the second enclosed volume.

[0021] In additional embodiments, the second enclosed volume is arranged in an under-water environment.

[0022] In some embodiments, the high-speed transportation system further comprises at least one walkway or guideway arranged within the at least one enclosed volume.

[0023] In certain embodiments, the at least one support structure comprises a plurality of support rings, and the system additionally comprises a plurality of support wires connected between two of the plurality of support rings, wherein the at least one flexible material is at least supported by the plurality of support wires.

[0024] In further embodiments, the plurality of support wires between adjacent support rings are configured with a 90° clocking.

[0025] In additional embodiments, the support wires comprise at least one of: steel, fibers, polymer materials, webbing, and filaments.

[0026] In embodiments, the tensile load is due at least in part to a pressure differential between the low-pressure environment of the enclosed volume, and an ambient pressure outside the enclosed volume.

[0027] In certain embodiments, the at least one flexible material comprises at least one of: a plastic membrane; a plastic membrane having embedded filaments; a layer of metal; a translucent material; and a transparent material.

[0028] In embodiments, the at least one flexible material is impermeable to air.

[0029] In additional embodiments, the system additionally comprises a propulsion system adapted to propel the at least one capsule through the enclosed volume; and a levitation system adapted to levitate the capsule within the enclosed volume.

[0030] Additional aspects of the present disclosure are directed to a structure, comprising at least one flexible material structured and arranged to withstand a tensile load; at least one support structure configured to support the flexible material and structured and arranged to withstand a compressive load, and at least one enclosed volume at least partially defined by the at least one flexible material, and the at least one enclosed volume being configured to be maintained as a low-pressure environment for a high-speed transportation system.

[0031] In additional embodiments, the structure further comprises at least one track along a transportation path within the at least enclosed volume, wherein the at least one track is configured for supporting a capsule configured for travel through the at least enclosed volume.

#### BRIEF DESCRIPTION OF THE DRAWINGS

[0032] The novel features which are characteristic of the systems, both as to structure and method of operation thereof, together with further aims and advantages thereof, will be understood from the following description, considered in connection with the accompanying drawings, in which embodiments of the system are illustrated by way of example. It is to be expressly understood, however, that the drawings are for the purpose of illustration and description only, and they are not intended as a definition of the limits of the system. For a more complete understanding of the disclosure, as well as other aims and further features thereof, reference may be had to the following detailed description of the disclosure in conjunction with the following exemplary and non-limiting drawings wherein:

[0033] FIG. 1 is a schematic view of a transportation system in accordance with embodiments of the present disclosure;

[0034] FIG. 2 illustrates a view of exemplary capsule for use in the transportation system in accordance with embodiments of the present disclosure;

[0035] FIG. 3 illustrates a schematic view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0036] FIG. 4 illustrates a schematic view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0037] FIG. 5 illustrates a schematic perspective view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0038] FIG. 6 illustrates a schematic perspective view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0039] FIG. 7 illustrates a schematic perspective view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0040] FIG. 8 illustrates a schematic view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0041] FIG. 9 illustrates a schematic view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0042] FIG. 10 illustrates a schematic view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0043] FIG. 11 illustrates a schematic view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0044] FIG. 12 illustrates a schematic view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0045] FIG. 13 illustrates a schematic view of a portion of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0046] FIG. 14 illustrates a schematic view of a portion of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0047] FIGS. 15A-15B illustrate schematic views of a portion of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0048] FIGS. 16A-16B illustrate schematic views of a portion of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0049] FIGS. 17A-17B illustrate schematic cross-sectional views of a portion of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0050] FIG. 18 illustrates a schematic view of a portion of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure;

[0051] FIGS. 19A-19B illustrate schematic views of a portion of exemplary low-pressure environment support structures in accordance with embodiments of the present disclosure;

[0052] FIGS. 20A-20B illustrate schematic views of a portion of an exemplary low-pressure environment support structure in accordance with embodiments of the present disclosure; and

[0053] FIG. 21 illustrates a schematic view of an exemplary low-pressure environment connector structure in accordance with embodiments of the present disclosure.

#### DETAILED DISCLOSURE

[0054] In the following description, the various embodiments of the present disclosure will be described with respect to the enclosed drawings. As required, detailed embodiments of the embodiments of the present disclosure are discussed herein; however, it is to be understood that the disclosed embodiments are merely exemplary of the embodiments of the disclosure that may be embodied in various and alternative forms. The figures are not necessarily to scale and some features may be exaggerated or minimized to show details of particular components. Therefore, specific structural and functional details disclosed herein are not to be interpreted as limiting, but merely as a representative basis for teaching one skilled in the art to variously employ the present disclosure.

[0055] The particulars shown herein are by way of example and for purposes of illustrative discussion of the embodiments of the present disclosure only and are presented in the cause of providing what is believed to be the most useful and readily understood description of the principles and conceptual aspects of the present disclosure. In this regard, no attempt is made to show structural details of the present disclosure in more detail than is necessary for the fundamental understanding of the present disclosure, such that the description, taken with the drawings, making apparent to those skilled in the art how the forms of the present disclosure may be embodied in practice.

[0056] As used herein, the singular forms “a,” “an,” and “the” include the plural reference unless the context clearly dictates otherwise. For example, reference to “a magnetic

material” would also mean that mixtures of one or more magnetic materials can be present unless specifically excluded.

**[0057]** Except where otherwise indicated, all numbers expressing quantities used in the specification and claims are to be understood as being modified in all instances by the term “about.” Accordingly, unless indicated to the contrary, the numerical parameters set forth in the specification and claims are approximations that may vary depending upon the desired properties sought to be obtained by embodiments of the present disclosure. At the very least, and not to be considered as an attempt to limit the application of the doctrine of equivalents to the scope of the claims, each numerical parameter should be construed in light of the number of significant digits and ordinary rounding conventions (unless otherwise explicitly indicated).

**[0058]** Additionally, the recitation of numerical ranges within this specification is considered to be a disclosure of all numerical values and ranges within that range (unless otherwise explicitly indicated). For example, if a range is from about 1 to about 50, it is deemed to include, for example, 1, 7, 34, 46.1, 23.7, or any other value or range within the range.

**[0059]** The various embodiments disclosed herein can be used separately and in various combinations unless specifically stated to the contrary.

**[0060]** Referring to FIG. 1, a transportation system 10 in accordance with aspects of the present disclosure is illustrated. In embodiments, the transportation system 10 comprises one or more capsules or transport pods 12 traveling through at least one enclosed structure (e.g., a tube) 14 between two or more stations 16. In one exemplary embodiment of the present disclosure, the capsules 12 of the transportation system 10 move through a low-pressure environment within the at least one enclosed structure 14. In accordance with certain aspects of the disclosure, a low-pressure environment includes (but is not limited to) any pressure that is below 1 atmosphere (or approximately 1 bar) at sea level.

**[0061]** Some elements of a high-speed transportation system are discussed in commonly-assigned U.S. application Ser. No. 15/007,783, entitled “Transportation System,” filed in the USPTO on even date herewith, the entire content of which is expressly incorporated by reference herein in its entirety.

**[0062]** In embodiments of the present disclosure, a system comprises one or more partially evacuated enclosed structures 14 that connect the stations 16 in a closed loop system. In embodiments, enclosed structures 14 may be sized for optimal air flow around the capsule 12 to improve performance and energy consumption efficiency at the expected or design travel speed. In accordance with aspects of the disclosure, the low-pressure environment in the enclosed structures 14 minimizes the drag force on the capsule 12, while maintaining the relative ease of pumping out the air from the tubes.

**[0063]** Referring now to FIG. 2, an exemplary and non-limiting depiction of a capsule or transport pod 12 of the transportation system is illustrated. In embodiments, the capsule 12 may be streamlined to reduce an air drag coefficient as the capsule 12 travels through the low-pressure environment of the at least one enclosed structure 14 of the transportation system. In accordance with aspects of the disclosure, in certain embodiments, a compressor arranged at the front end of the capsule is operable to ingest at least a portion of the incoming air and pass it through the capsule (instead of dis-

placing the air around the vehicle). For example, as schematically shown in the exemplary embodiment of FIG. 2, the capsule 12 may include a compressor at its leading face. In embodiments, the compressor is operable to ingest oncoming air and utilize the compressed air for the levitation process (when, for example, the capsules are supported via air bearings that operate using a compressed air reservoir and aerodynamic lift). Additionally, as schematically shown in the exemplary embodiment of FIG. 2, in embodiments, the compressed air may be used to spin a turbine, for example, located at the rear end of the capsule, to provide power to the capsule 12. As schematically shown in the exemplary embodiment of FIG. 2, the capsule 12 may also include a motor structured and arranged to drive the compressor, and a battery for storing energy, e.g., derived from the turbine. The capsule 12 also includes a payload area, which may be configured for humans, for cargo, and/or for both humans and cargo.

**[0064]** When the enclosed structure that forms the channel for the transit or transportation corridor is a tube structure, the tube structure operates under heavy compression due to the difference in pressure between the near-vacuum inside of tube and the atmospheric pressure outside the walls of the tube. This loading can cause the cylinder walls to buckle. Therefore, the tube structure design may not be limited by strength of materials, but rather by shell thickness, geometry modifications, and material stiffness properties. The tube thickness may require increased thickness or a more complex geometry than it would if the structure were strength-limited only, and so the cost increases for this component of the transportation system. Since a very large fraction of the transportation system cost is in the enclosed structure materials and construction, it is important to optimize the efficiency and cost of this structure to as great an extent as possible.

**[0065]** In accordance with aspects of the disclosure, the tube structure can be replaced with alternative structures, such as an enclosed structure for containing low-pressure environments that is structured and arranged to withstand the pressure load in tension (at least partially). A structure in pure tension cannot buckle, and therefore can often be taken to a higher stress state than a structure loaded primarily in compression. Thus, in accordance with aspects of the disclosure, utilizing a tension-loaded structure allows for more efficient use of the material. By utilizing material efficiently (that is, by utilizing a higher fraction of the material allowable stress) and loading each structural element to be strength-limited, as opposed to buckling-limited (which may require more material e.g., greater thickness), the amount of construction material may be reduced. This reduction in material may result in a substantial reduction in cost.

**[0066]** In accordance with aspects of the disclosure, in embodiments, a thin membrane material is exposed to the pressure differential and shaped (e.g., using a support structure) specifically to act in tension. This membrane is supported continuously or discretely at increments by compression (e.g., primarily in compression) structures that determine the shape of the membrane and keep the membrane from collapsing under load. Embodiments of the present disclosure may comprise a material (e.g., a small amount of thin material) to provide the pressure barrier, and a support structure (that withstands the compression loads directly) supporting the pressure barrier. By implementing aspects of the disclosure, these low-pressure environment structures can avoid the problem of buckling (or higher material costs) that may be experienced with tubular structures.

[0067] FIG. 3 illustrates a schematic view of an exemplary low-pressure environment structure 300 in accordance with embodiments of the present disclosure. As shown in FIG. 3, the structure 300 includes at least one track support platform 305 for supporting at least one track configured for capsules 12 traveling through the transportation system. In embodiments, the at least one track support platform 305 may be supported on at least one pillar 310 in contact with the ground 335. A vertical support 315 is arranged on (or between) the at least track support platform 305, and includes an attachment structure 325 at the top thereof. As shown in FIG. 3, two horizontal supports 320 extend approximately horizontally from the track support platform 305, and each includes an attachment structure 325 at a respective end thereof. Cables 370 may be connected to respective attachment structures 325 and the pillar 310 and in tension to counter loading from below the track support platform 305 and horizontal supports 320 by atmospheric pressure. The vertical support 315 and the two horizontal supports 320 may be arranged approximately regularly-spaced along the path of the transportation system (e.g., approximately every 100-150 feet).

[0068] In accordance with aspects of the disclosure, as shown in FIG. 3, at least one sheet of flexible material 330 (or a membrane) is attached between the attachment structures 325 to create an enclosed environment 345. The flexible material 330 is held in tension between respective attachment structures 325 and is structured and configured to support a tension load. In embodiments, the attachment structures 325 may comprise, for example, hooks, loops, fasteners, and/or adhesives. In some embodiments (not shown), instead of (or in addition to) the cable 370, the membrane (or flexible material) 330 may continue wrapping around until it reaches the base of the pylon that supports the track.

[0069] When air is evacuated in the enclosed environment 345 (e.g., to create the low-pressure environment), a pressure differential will exist between the outside environment and the enclosed environment 345, wherein the pressure inside the enclosed environment 345 (e.g., less than 1 atmosphere) will be lower than the outside ambient pressure (e.g., 1 atmosphere). Accordingly, due to the pressure differential, forces 340 will act on the flexible material 330 causing a tension 350 in the flexible material 330. In accordance with aspects of the disclosure, the flexible material 330 is structured and arranged to withstand the tension. Moreover, as the flexible material 330 is subjected to a tensile load 350 (rather than a compressive load) the flexible material 330 can withstand the load while utilizing less material.

[0070] As shown in FIG. 3, the tension (represented by arrow 350) in the flexible material 330 (as well as the weight of the structure) induces a compressive load (represented by arrow 355) in the vertical support 315 and/or compressive loads (represented by arrow 360) in each of the two horizontal supports 320. Within the context of the present application, while some elements are described as being in compression, it should be understood that these structures may be primarily in compression (with some tension as well). In accordance with further aspects of the disclosure, the vertical support 315 and the two horizontal supports 320 are structured and configured to withstand these compressive loads 355, 360 directly.

[0071] In such a manner, in accordance with aspects of the disclosure, an alternative structure to the tubular structure may be utilized in the high-speed transportation system, which alternative structure may be less expensive to manu-

facture and install. By utilizing such an alternative structure, the overall costs for the transportation system may be reduced.

[0072] In embodiments, the flexible material 330 may comprise a thin plastic film layered around high strength filaments, e.g., Kevlar or carbon fiber. In accordance with aspects of the disclosure, utilizing these filaments in such a structure improves the strength and load path of the material and allows the filaments to remain thin, while accommodating and/or allowing larger radiuses of curvature with potentially larger spans between areas of support and thinner overall membrane than an unreinforced film. In accordance with aspects of the disclosure, in some embodiments, the fibers may also act as tear stops and prevent a breach in the flexible material 330 from spreading. In further contemplated embodiments, the flexible material 330 may comprise a relatively thin layer of metal (e.g., steel). Further embodiments may utilize a flexible material 330 comprising pre-manufactured sail materials. It should be understood that flexible material may include materials not generally considered flexible. For example, further embodiments may utilize a thin piece of glass or a carbon fiber sheet that is thin so as to take the appropriate curvatures and/or shapes.

[0073] In embodiments, the vertical and horizontal supports may comprise steel, reinforced concrete, and/or composite materials, for example. In accordance with aspects of the disclosure, as shown in FIG. 3, the structure 300 is symmetrical, which provides a more balanced structure.

[0074] In embodiments, the flexible material 330 may be transparent or translucent, which, for example, allows ambient light to enter the enclosed environment 345. In accordance with aspects of the disclosure, when the flexible material 330 is transparent or translucent, viewers outside of the enclosed environment 345 may be able to observe passing capsules 12 in the transportation system. Additionally, in some embodiments, the capsule 12 may have windows, which, when the flexible material 330 is transparent or translucent, provides passengers in the capsule 12 a view of the outside environment.

[0075] FIG. 4 illustrates a schematic view of an exemplary low-pressure environment structure 400 in accordance with embodiments of the present disclosure. As shown in FIG. 4, with this exemplary structure 400, at least one track support platform 405 is arranged on the ground 335. A vertical support 415 is arranged on the at least one track support platform 405 (or, for example, between two track support platforms), and includes an attachment structure 325 at the top thereof. In accordance with aspects of the disclosure, as shown in FIG. 4, at least one sheet of flexible material 330 (or a membrane) is attached between attachment structure 325 and respective ends of the track support platform 405 to create an enclosed environment 445 having a transportation path for at least one capsule 12. A sealing layer (i.e., a gas impermeable layer) may be utilized to prevent air from permeating through the support platform 405. The flexible material 430 is held in tension between the attachment structure and the respective ends of the track platform 405.

[0076] FIG. 5 illustrates a schematic perspective view of an exemplary low-pressure environment structure 500 in accordance with embodiments of the present disclosure. As shown in FIG. 5, with this exemplary structure 500, at least one track support platform 505 is arranged on the ground (not shown) or a plurality of spaced supports (not shown). A vertical support 515 is arranged on (or between) the at least one track

platform **505**, and includes an attachment structure **525** at the top thereof. With this exemplary structure **500**, longitudinal supports **550** are arranged between and connected to the vertical supports **515** (or the attachment structures **525** on the vertical supports **515**). In accordance with aspects of the disclosure, the longitudinal supports **550** are configured to increase the structural stability of the transportation structure. In embodiments, the longitudinal supports **550** may be configured to flex to account for any relative movements of the vertical supports **515**. In further embodiments, the longitudinal supports **550** may include one or more expansion joints to, for example, account for any relative movements of the vertical supports **515** (e.g., due to thermal expansion and/or contraction, seismic events, and/or weather). In embodiments, the longitudinal supports **550** may be support beams, e.g., I-beams. In further contemplated embodiments, the longitudinal supports **550** may be fiber, cable, filament, or wire material, for example.

[0077] In accordance with aspects of the disclosure, as shown in FIG. 5, at least one sheet of flexible material **330** (or a membrane) is attached to attachment structure **525** and respective ends of the track platform **505** to create an enclosed environment **545**. In embodiments, the at least one sheet of flexible material **330** may “drape” or hang over the support beams **550** (while, in certain embodiments, being connected thereto by connectors, e.g., clips) with respective ends of the flexible material **330** connected to the respective ends of the track platform **505**. In further contemplated embodiments, the at least one sheet of flexible material **330** may comprise one sheet of flexible material **330** connected between the longitudinal supports **550** and a respective end of the track platform **505**, and another sheet of flexible material **330** connected between the longitudinal supports **550** and the other respective end of the track platform **505**. Additionally, the disclosure contemplates that a series of sheets of flexible material **330** will be connected to one another in order to create the enclosed environment **545**. In embodiments, the connections between adjacent sheets of flexible material **330** may be formed with seams utilizing, e.g., stitching, welds, adhesives, and/or fasteners. As shown in the schematic depiction of FIG. 5, the vertical supports **515** may be arranged approximately regularly-spaced from each other along the path of the transportation system by a distance **555** (e.g., approximately every 100 to 150 feet with other distances contemplated by the disclosure).

[0078] FIG. 6 illustrates a schematic perspective view of an exemplary low-pressure environment structure **600** in accordance with embodiments of the present disclosure. In contrast to the exemplary low-pressure environment structure **500** (in which the vertical supports **515** are connected by longitudinal supports **550**), no longitudinal supports are provided between the spaced vertical supports **515** with structure **600**. As such, as schematically depicted in FIG. 6, the sheet of flexible material **330** may have “drooping” regions **605** between spaced vertical supports **515**, in a similar manner to a circus tent.

[0079] FIG. 7 illustrates a schematic perspective view of an exemplary low-pressure environment structure **700** in accordance with embodiments of the present disclosure. In contrast to the exemplary low-pressure environment structure **500** (which includes spaced vertical supports **515** with longitudinal supports **550** connected between the spaced vertical supports **515**), with structure **700**, at least one wall **715** is provided along the transportation path. The wall **715** is structured

and configured to support the flexible material **330**. In embodiments, the connections between adjacent sheets of flexible material **330** may be formed with seams **710** utilizing, e.g., stitching, welds, adhesives, and/or fasteners. With an exemplary embodiment, adjacent panels of flexible material might be joined as often as every 3"-6", which, for example, may be the width of a roll of material (e.g., a large continuous roll). In certain embodiments, seams could be arranged longitudinally and/or around the circumference of the tent profile, so there are seam joints in multiple directions for increased strength.

[0080] Additionally, in accordance with aspects of the disclosure, the at least one wall **715** may be configured to be non-permeable to air, such that when the flexible material **330** is secured to the wall **715** and the track platform **705**, two enclosed environments are formed, e.g., a first enclosed environment **745** and a second enclosed environment **745'**. With such a structure, if the low-pressure environment in one of the two enclosed environments is lost (e.g., due to a puncture of the flexible material **330**), the low-pressure environment is still maintained in the other enclosed environment. In further aspects of the disclosure, by providing a wall **715** such that two enclosed environments are formed, e.g., a first enclosed environment **745** and a second enclosed environment **745'**, these two enclosed environments can be configured having different operating pressures. For example, one enclosed environment may be maintained as a low-pressure environment, and the other enclosed environment may be maintained as an atmospheric pressure environment.

[0081] While not shown in FIG. 7, in embodiments, the wall **705** may include perforations, holes, and/or windows there-through. In accordance with aspects of the disclosure, with such a structure, the perforations, holes, and/or windows allow for air to pass from one side of the wall to the other side, which may reduce forces acting on an interior of the enclosed environment **745**, for example, when two capsules **12** pass one another in the transportation system. Additionally, in accordance with aspects of the disclosure, such perforations, holes, and/or windows may reduce the overall weight of the wall **705**, and thus reduce the structural requirements for other support structures (e.g., pillars, track platform) that support such wall **705**.

[0082] FIG. 8 illustrates a schematic view of an exemplary low-pressure environment structure **800** in accordance with embodiments of the present disclosure. As shown in FIG. 8, the structure **800** includes at least one track support platform **805** for supporting capsules **12**, **12'** traveling through the transportation system. In embodiments, the at least one track support platform **805** may be supported on at least one pillar **310** in contact with the ground **335**. A vertical support **315** is arranged on (or between) the at least one track support platform **805**, and includes an attachment structure **325** at the top thereof. As shown in FIG. 8, two angled supports **820** extend from the track support platform **805**, and each include an attachment structure **325** at the respective ends thereof. In embodiments, the vertical supports **315** and the pairs of two angled supports **820** may be arranged approximately regularly-spaced along the path of the transportation system (e.g., every 100 feet). In embodiments, cables (not shown) may be connected to respective attachment structures and the pillar **310** and in tension to counter loading from below the track support platform **805** by atmospheric pressure. In further embodiments (not shown), instead of (or in addition to) the

cable, the membrane (or flexible material) 330 may continue wrapping around until it reaches the pylon (or pillar) 310 that supports the track.

[0083] In accordance with aspects of the disclosure, as shown in FIG. 8, at least one sheet of flexible material 330 (or a membrane) is attached between the attachment structures 325 and respective ends of the track support platform 805 to create an enclosed environment 845. The flexible material 330 is held in tension between respective attachment structures 325 and between the attachment structures 325 and the respective ends of the track support platform 805.

[0084] As shown in FIG. 8, in accordance with aspects of the disclosure, the tensions 850 in the flexible material 330, caused by the pressure differential between the outside environment and enclosed environment 845, induce a compressive load 855 in the vertical support 315, compressive loads 860 in each of the two angled supports 820, and compressive loads 865 in the track support platform 805. In accordance with further aspects of the disclosure, the vertical support 315, the two angled supports 820, and the track support platform 805 are structured and configured to withstand these compressive loads 855, 860, and 865. In embodiments, the angled supports 820 may comprise support beams (e.g., I-beams) or may comprise walls (e.g., with or without perforations, holes or windows).

[0085] In accordance with further aspects of the disclosure, as shown with the exemplary structure 800, four capsule paths are arranged on the track support platform 805, for example, providing paths in each direction for two types and/or sizes of capsules 12, 12'. For example, the larger capsules 12 may be configured as cargo-carrying capsules and the smaller capsules 12' may be configured as passenger-carrying capsules, or vice versa.

[0086] FIG. 9 illustrates a schematic view of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure. As shown in FIG. 9, the structure 900 includes at least one track support platform 905 for supporting capsules 12 traveling through the transportation system. In embodiments, the at least one track support platform 905 may be supported on pillars (not shown) or the ground (not shown). A vertical support 315 is arranged on (or between) the at least one track support platform 905, and includes an attachment structure 325 at the top thereof. As shown in FIG. 9, two angled supports 920 extend from the vertical support 315, and each include an attachment structure 325 at the respective ends thereof. In embodiments, the vertical support 315 and the pairs of two angled supports 920 may be arranged approximately regularly-spaced along the path of the transportation system (e.g., every 100 to 150 feet).

[0087] In accordance with aspects of the disclosure, as shown in FIG. 9, at least one sheet of flexible material 330 (or a membrane) is attached between the attachment structures 325 and respective ends of the track support platform 905 to create an enclosed environment 945. The flexible material 330 is held in tension between respective attachment structures 325 and between the attachment structures 325 and the respective ends of the track support platform 905.

[0088] FIG. 10 illustrates a schematic view of an exemplary low-pressure environment structure 1000 in accordance with embodiments of the present disclosure. As shown in FIG. 10, structure 1000 includes at least one track support platform 1005 for supporting capsules 12 traveling through the transportation system. In embodiments, the at least one track support platform 1005 may be supported on pillars (not shown)

or the ground (not shown). With this exemplary embodiment, three vertical supports 1015 are arranged on the at least one track support platform 1005 (in the approximate middle of and on each approximate end thereof), and each include an attachment structure 325 at the tops thereof. As shown in FIG. 10, two downwardly-angled supports 1020 extend from respective ends of the track support platform 1005, and each include an attachment structure 325 at the respective ends thereof. In embodiments, the vertical support 1015 and the two angled supports 1020 may be arranged approximately regularly-spaced along the path of the transportation system (e.g., every 100 to 150 feet).

[0089] In accordance with aspects of the disclosure, as shown in FIG. 10, at least one sheet of flexible material 330 (or a membrane) is attached between the attachment structures 325 to create an enclosed environment 1045. The flexible material 330 is held in tension between respective attachment structures 325. In embodiments, cables (not shown) may be connected to respective attachment structures and the pillar (not shown) and in tension to counter loading from below the track support platform 1005 and supports 1020 by atmospheric pressure. In further embodiments (not shown), instead of (or in addition to) the cable, the membrane (or flexible material) 330 may continue wrapping around until it reaches the pylon (not shown) that supports the track.

[0090] In embodiments, tension forces 1050 in the flexible material 330 may cause an upward pull 1055 on structures to which the ends of the flexible material 330 are attached. Additionally, while this depicted embodiment utilizes vertical supports 315 that are structured and arranged to be in essentially compression only, if some supports are arranged at an upward angle (for example, as with the embodiment of FIG. 9), the exit angle of the angled supports may induce a tension (e.g., an upwardly directed tension). As shown in FIG. 10, in accordance with aspects of the disclosure, the two angled supports 1020 (which are arranged as downwardly angled) are structured and arranged to create a counter force 1060 to the upward pull 1055 caused by the tension 1050 in the flexible material 330. Such a structure may also be used to counteract an induced tension caused by upwardly angled supports (e.g., as shown in FIG. 9). Thus, in accordance with aspects of the disclosure, utilizing such downwardly-angled supports 1020 may provide a more stable and secure structure 1000.

[0091] FIG. 11 illustrates a schematic view of an exemplary low-pressure environment structure 1100 in accordance with embodiments of the present disclosure. As shown in FIG. 11, structure 1100 includes at least one track support platform 1105 for supporting capsules 12" traveling through the transportation system. In contrast to the previously discussed embodiments, with this exemplary embodiment, the capsule 12" is configured to ride along a track arranged above the capsule 12". Additionally, with this exemplary embodiment, the track support platform 1105 is configured with a single transportation path. As should be understood, the disclosure contemplates that a support platform can be configured to support, for example two transportation paths, four transportation paths, or some other number of transportation paths.

[0092] With this exemplary embodiment, the at least one track support platform 1105 (or guideway) is supported by an arch structure 1110, which is arranged on the ground 335. The arch structure 1110 is connected to depending supports 1120 (e.g., with fasteners, bolts, and/or welding), and the depending supports 1120 support the track support platform 1105

(e.g., with fasteners, bolts, brackets, and/or welding). The structure 1100 also includes lower attachment structures 1125, which may be secured to the arch structure 1110. Similarly to other embodiments, the arch structure 1110 and the two depending supports 1120 may be arranged approximately regularly-spaced along the path of the transportation system (e.g., every 100 to 150 feet). In accordance with aspects of the disclosure, as shown in FIG. 11, at least one sheet of flexible material 330 (or a membrane) is attached between the attachment structures 1125 and the ends of the track support platform 1105 to create an enclosed environment 1145.

[0093] FIG. 12 illustrates a schematic view of an exemplary low-pressure environment structure 1200 in accordance with embodiments of the present disclosure. In accordance with aspects of the disclosure, structure 1200 may be used in an under-water environment, and may comprise two levels of membranes 330, 1255. In accordance with aspects of the disclosure, the outer level creates a pocket with the inner level and is inflated with a gas, such as air, at a pressure slightly higher than the pressure in the ambient environment. The second membrane 330 separates the air-filled pocket from the near vacuum transportation corridor. This embodiment has a hydrodynamic outer profile. Should a leak be present between the air-filled pocket and the underwater environment a small amount of gas will be lost to the underwater environment. If a leak is present between the air filled volume and the near vacuum area, gas will enter the vacuum area and can easily be pumped out. This leads to an improved ability to handle leaks.

[0094] As shown in FIG. 12, structure 1200 includes a double-membrane structure, e.g., a plurality of sheets of flexible material (or membranes), for example, two levels of membranes. More specifically, structure 1200 includes flexible material 330, which defines a first enclosed environment 1245, and which is maintained as a low-pressure environment. As shown in FIG. 12, structure 1200 also includes flexible material 1255 (which may be the same material(s) as flexible material 330 or different materials), which defines a second enclosed environment 1260. As shown in FIG. 12, the pressure outside of the structure 1200 is  $P_{depth}$ , which is dependent upon the depth of the structure. In accordance with aspects of the disclosure, the second enclosed environment 1260 is maintained at a pressure that is, for example, higher (e.g., slightly higher) than the ambient pressure outside of the structure, e.g.,  $>P_{depth}$  or  $P_{depth}+1\%$ , with other higher pressures contemplated. With such an arrangement, if the flexible material 1255 is punctured, the higher pressure (e.g.,  $P_{depth}+1\%$ ) in the second enclosed environment 1260 pushing outwardly against the seawater will prevent or minimize any incoming water through the puncture and into the second enclosed environment 1260. Instead, air will flow from the second enclosed environment 1260 to the underwater environment, e.g., a small amount of gas will be lost to the underwater environment. If a leak is present between the air filled volume and the near vacuum area, gas will enter the vacuum area and can easily be pumped out with existing air pumps (e.g., used to maintain the low-pressure environment). In accordance with aspects of the disclosure, this exemplary structure 1200 leads to an improved ability to handle leaks. In embodiments, the structure 1200 may also include pumps (not shown) to remove any seawater that may enter the second enclosed environment 1260.

[0095] In accordance with aspects of the disclosure, as shown in FIG. 12, at least one sheet of flexible material 330

(or a membrane) is attached between the attachment structures 1225 to create an enclosed environment 1245. As the pressure in the second enclosed environment 1260 (e.g.,  $P_{depth}+1\%$ ) is greater than the pressure in the first enclosed environment 1245 (e.g., low-pressure), the flexible material 330 is held in tension between respective attachment structures 1225.

[0096] As shown in FIG. 12, the structure 1200 includes at least one track support platform 1205 for supporting capsules 12, 12" traveling through the transportation system. With this exemplary embodiment, the structure 1200 includes passages for two capsules 12, which ride above (or on) respective tracks (not shown) arranged on the track support platform 1205, and also includes passages for two capsules 12', which ride below (or hang from) respective tracks (not shown) arranged on the track support platform 1205.

[0097] A vertical support 1215 is arranged on (or between) the at least track support platform 1205, and includes attachment structures 1225 at the respective ends thereof. As shown in FIG. 12, with this exemplary embodiment, two horizontal supports 1220 extend approximately horizontally from the at least track support platform 1205, and each include an attachment structure 1225 at the respective ends thereof. In embodiments, the vertical support 1215 and the two horizontal supports 1220 may be arranged approximately regularly-spaced along the path of the transportation system (e.g., every 100 to 150 feet).

[0098] As schematically depicted in FIG. 12, a plurality of supports 1250 are structured and arranged to connect the structure 1200 to the ground 1235 (e.g., the sea floor) via a secure attachment to the attachment structures 1225. In embodiments, the supports 1250 may be arranged to provide a redundant support structure. In embodiments, the supports 1250 may be pillars, beams, or other relatively rigid structure. In other contemplated embodiments, the supports 1250 may be flexible supports (e.g., cables, or wires) that are structured and arranged to maintain a relative position and/or orientation of the structure 1200. In accordance with aspects of the disclosure, the enclosed low-pressure environment 1245 will render the structure 1200 buoyant. In certain embodiments, the structure 1200 may additionally include one or more buoyancy devices, e.g., ballasts and/or buoys (not shown) structured and arranged to provide additional buoyancy to the structure 1200.

[0099] FIG. 13 illustrates a schematic view of a cutaway portion of an exemplary low-pressure environment structure 1300 in accordance with embodiments of the present disclosure. As shown in FIG. 13, the structure 1300 includes at least one track support platform 1305 for supporting capsules 12 traveling through the transportation system. In embodiments, the at least one track support platform 1305 may be supported on pillars (not shown) or the ground (not shown). A vertical support 1315 is arranged on (or along) the at least one track support platform 1305. As shown in FIG. 13, two angled supports 1320 extend from the vertical support 1315, and each include an attachment structure 1325 at the respective ends thereof. In embodiments, a vertical support 1315 and the angled supports 1320 may be arranged in an approximately regularly-spaced relationship along the path of the transportation system (e.g., every 100 to 150 feet).

[0100] In accordance with aspects of the disclosure, as shown in FIG. 13, at least one sheet of flexible material 1330 (or a membrane) is attached between the attachment structures 1325 and an end of the track support platform 1305 to

create an enclosed environment 1345. The flexible material 1330 is held in tension between respective attachment structures 1325 and between the attachment structures 1325 and an end of the track support platform 1305. In some embodiments, the structure may include at least one walkway 1350, e.g., a maintenance walkway, adjacent the capsule transportation path that is within the enclosed environment 1345.

[0101] In accordance with additional aspects of the disclosure, the lengths and diameters (or widths) of support structures (e.g., of the vertical support 1315 and/or the two angled supports 1320 with the example of FIG. 13) may be optimized to balance material usage and strength. For example, a minimum amount of material may be used to achieve the design strength (e.g., with a safety factor or margin).

[0102] FIG. 14 illustrates a schematic view of a portion of an exemplary low-pressure environment structure in accordance with embodiments of the present disclosure. Embodiments include the structure depicted in FIG. 14 alone, and the structure depicted in FIG. 14 together with a corresponding approximate mirror-image structure, which is not shown (e.g., arranged to the left of the depicted embodiment).

[0103] As shown in FIG. 14, the structure 1400 includes at least one track support platform 1405 for supporting capsules 12 traveling through the transportation system. In embodiments, the at least one track support platform 1405 may be supported on pillars (not shown) or the ground (not shown). A vertical support 1415 is arranged on (or along) the at least one track support platform 1405, with an attachment structure 1425 on an end thereof. As should be understood from FIG. 14, two angled supports 1420 (only one shown) extend from the track support platform 1405, and each includes an attachment structure 1425 at the respective ends thereof. In embodiments, the vertical support 1415 and the two angled supports 1420 may be arranged approximately regularly-spaced (e.g., at regularly-spaced intervals) along the path of the transportation system. In certain embodiments, the angled supports 1420 may be solid or opaque. In other contemplated embodiments, the angled supports 1420 may be transparent, translucent, and/or include holes (or windows) there-through.

[0104] In accordance with aspects of the disclosure, as shown in FIG. 14, at least one sheet of flexible material 1430 (or a membrane) is attached between the attachment structures 1425 and an end of the track support platform 1405 to create an enclosed environment 1445. The flexible material 1430 is held in tension between respective attachment structures 1425 and between the attachment structures 1425 and an end of the track support platform 1405.

[0105] In accordance with aspects of the disclosure, in some embodiments different flexible materials may be used for different portions of the structure 1400. For example, in some embodiments, a higher strength material (e.g., a membrane embedded with steel fibers) may be used as a flexible material between the vertical support 1415 and an angled support 1420, and a lower-strength material (which may be, for example, at least partially see-through) may be used as a flexible material between angled support 1420 and the track support platform 1405.

[0106] FIGS. 15A-15B illustrate schematic views of a portion of an exemplary low-pressure environment structure 1500 in accordance with further embodiments of the present disclosure. As shown in FIG. 15A, structure 1500 includes a plurality of support rings 1505 between which support wires 1510 (e.g., cables, fibers, webs, or filaments) are attached at attachments 1515 (e.g., hooks, fasteners). The support rings

1505 are structured and configured as compression rings to withstand the compressive forces 1555 due to the support wires, which are in tension 1550. With this exemplary embodiment, structure 1500 places the tension into fibers or support wires 1510. The support rings 1505, which may be made of materials strong in compression, such as concrete, for example, are configured as the main elements to withstand the compressive forces. The support rings 1505 are spaced at a distance (e.g., a specified and/or regularly) from each other, and each support ring 1505 having a central axis that is substantially parallel to the other support rings 1505 along the transportation path. A plurality of high tensile, high strength support wires 1510 (or support fibers), such as steel or aromatic polyamide fibers, are attached to an outer circumference of each ring 1505, and connect the rings 1505. In embodiments, the support wires 1510 (or fibers) may be wound around the support rings 1505 such that a position of a respective fiber rotates about the ring by some angle for each successive ring. Thus, even though, in embodiments, the fibers are tensioned to be fairly straight, the structure 1500 may appear to have hyperbolic shape from the side. In accordance with aspects of the disclosure, this angular pattern also allows the structure 1500 to efficiently resist shear loads (side loads). A flexible material 1520 is arranged around and supported by the plurality of support wires 1510 and attached to the support rings 1505 to create an enclosed environment 1545 (which may be configured as a low-pressure environment). For example, an "outer skin" flexible material 1520 comprising, for example, a polymer, such as polyethylene, a metal, or another material impermeable to air, is wrapped around the outside surface of the fiber mesh and support rings 1505 (or compression rings) to form a "tube."

[0107] This embodiment may also utilize, for example, a flexible material 1520 comprising a thin plastic film layered around high strength filaments, e.g., Kevlar or carbon fiber. In accordance with aspects of the disclosure, utilizing these filaments in such a structure improves the strength and load path of the material and allows the filaments to remain thin, while accommodating and/or allowing larger radiuses of curvature with potentially larger spans between areas of support and thinner overall membrane than an unreinforced film. In accordance with aspects of the disclosure, in some embodiments, the fibers on or embedded in the flexible material 1520 may also act as tear stops and prevent a breach in the flexible material 1520 from spreading.

[0108] As shown in FIGS. 15A and 15B, with an exemplary and non-limiting embodiment, the support wires 1510 may have a 90° clocking (e.g., both -90° clocking and +90° clocking) between respective support rings 1505. For example, with a 90° clocking arrangement, a support wire 1510 is attached to a first support ring at the "12 o'clock" position and is attached to the second support ring at the "3 o'clock" position (i.e., 90° clockwise). A second support wire 1510 is also attached to the first support ring 1505 at the "12 o'clock" position and is attached to the second support ring 1505 at the "9 o'clock" position (i.e., 90° counter-clockwise). By attaching two support wires 1510 from each clock position (i.e., from each of twelve points on the first support ring 1505) to twelve points on a second support ring, in this manner (e.g., with the 90° clocking), a support structure as shown in FIG. 15B is obtained. In accordance with aspects of the disclosure, such a 90° clocking provides high (e.g., maximum) effect of angle while allowing sufficient cross-sectional area for capsule passage there-through. While the exemplary embodi-

ment has twelve connection points **1515** on each support ring, the disclosure contemplates that greater (or fewer) connection points **1505** may be utilized.

[0109] In embodiments, the support wires **1510** may comprise steel, Dyneema®, fabrics, high-strength fibers, amongst other contemplated materials having suitable properties. In embodiments, the flexible material **1520** may include a plastic membrane, for example, having UV-resistance. In further embodiments, for example, fibers (e.g., carbon fibers) may be infused in flexible material (or fabric) or along the flexible material.

[0110] In embodiments, plastic materials could be melt bonded together quickly and cheaply in order to seal the structure between “tube” sections. An alternative embodiment may use any number of metal materials for the flexible material **1520**. Another alternative embodiment may use plastic materials that provide sections that are transparent to light so that passengers inside the pod are able to see out.

[0111] In accordance with aspects of the disclosure, structure **1500** may be easier to manufacture due to for example, lighter and/or cheaper materials, e.g., as compared to a steel tube sized to provide an equivalent capsule passageway. Thus, by implementing such a structure **1500**, the costs for manufacturing and installing the transportation system may be reduced, lowering the costs of implementation for the transportation system.

[0112] FIGS. 16A-16B illustrate schematic views of a portion of an exemplary low-pressure environment structure **1600** in accordance with embodiments of the present disclosure. As shown in FIG. 16A, structure **1600** comprises a plurality of structures **1500** connected to one another (in embodiments, with adjacent shared support rings **1505** between the plurality of support wires **1510**). In embodiments, the support rings **1505** may be spaced (e.g., approximately regularly) from one another by a distance **1610**. In some exemplary and non-limiting embodiments, the distance **1610** may be approximately every 12 meters.

[0113] As shown in FIG. 16A, an anchor structure **1605** (e.g., an “end-cap”) may be arranged on at least one end of the tube path. In accordance with aspects of the disclosure the anchor structure **1605** may be configured to withstand the tension forces acting along the transportation path (for example, in a similar manner to anchor structures for suspension bridges). In some embodiments, the anchor structure **1605** may comprise steel and/or concrete. In some embodiments, the anchor structure **1605** attaches the support wires **1510** to the ground so as to bear the tension of the tube.

[0114] FIG. 16B illustrates a schematic view of a portion of an exemplary low-pressure environment structure **1600'** in accordance with embodiments of the present disclosure. As shown in FIG. 16B, a plurality of anchor structures **1605** may be arranged on ends of the tube path portions. In some embodiments, the anchor structures **1605** may be securely attached (e.g., cemented, welded, fastened) to, e.g., the top portions of respective pylons (or pillars) **1615** structured and arranged on the ground **1620**. In accordance with aspects of the disclosure the anchor structure **1605** and the pylons **1620** may be configured to provide offsetting forces **1625**, **1630** to withstand (or counter) the tension forces **1635** and gravitational forces **1650** acting along the transportation path (for example, in a similar manner to support structures for suspension bridges). In embodiments, the support rings **1505** (or compression rings) may be used as connections to additional pylons (not shown) for additional structural support. There

can also be additional anchor structures, similar to the anchor structures **1605**, which are configured to connect different spans of the tube, so that the tension is maintained in the span between the midcaps.

[0115] With an exemplary and non-limiting embodiment, three or four support rings **1505** may be spaced (e.g., approximately regularly) between pylons (or pillars), which may be spaced approximately every 50 meters.

[0116] These exemplary embodiments differ from a tubular structure designed in compression. The hyperboloid tensile structure has the advantage of not having to withstand substantial buckling forces, which may be a problem for compressed structures. Instead, compression forces are concentrated in a relatively small fraction of the tube, the support rings **1505** (e.g., the compression rings). Because the support rings **1505** may not bear any tensile loads, they can be made of concrete, as opposed to steel, which may reduce costs. Since tensile structures are much more efficient in converting ultimate material strength to load bearing capacity, tensile structures offer a potential savings in amount and cost of material. Another advantage of these embodiments is the structure's ability to deal with thermal expansion. For example, pipeline materials may shrink or contract along their length, creating additional stress forces within the system. In accordance with aspects of the disclosure, the hyperboloid structure, however, will naturally deal with contraction and expansion. The fibers will contract or expand, thus increasing or decreasing tension within the operating bounds of the design. Thus, in accordance with aspects of the disclosure, the hyperboloid tube structure may be simpler to construct, since, for example, no special joints (e.g., expansion joints) may be necessary.

[0117] FIGS. 17A-17B illustrate schematic cross-sectional views of a portion of an exemplary low-pressure environment structure **1700** in accordance with embodiments of the present disclosure. As shown in FIG. 17A, structure **1700** includes a plurality of support rings **1705** between which support wires **1510** (e.g., cables, fibers, webs) are attached at attachments **1515** (e.g., hooks, fasteners). The support rings **1705** are structured and configured as compression rings to withstand the compressive forces due to the support wires **1510**, which are in tension. A flexible material **1520** is arranged around and supported by the plurality of support wires **1510** and attached to the support rings **1705** to create an enclosed environment **1745** (which may be configured as a low-pressure environment). In another exemplary embodiment, a flexible material **1520** is arranged around and supported by the plurality of support wires **1510** and the support rings **1705** to create an enclosed environment **1745**.

[0118] As schematically illustrated in FIGS. 17A and 17B, a track support platform **1715** is arranged in the enclosed environment **1745** of the structure **1700**. The track support platform **1715** is structured and configured to provide at least one transportation path for a capsule **12**. The track support platform **1715** may be supported by platform supports **1710**, which may be secured to adjacent support rings **1705**. In certain embodiments, the track support platform **1715** and the platform supports **1710** may be structured and configured to provide additional stiffness to the structure **1700** (or to a plurality of structures **1700** connected together).

[0119] FIG. 18 illustrates a schematic view of a portion of an exemplary low-pressure environment structure **1800** in accordance with embodiments of the present disclosure. As shown in FIG. 18, structure **1800** includes at least one track

support platform **1805** for supporting capsules **12** traveling through the transportation system. In embodiments, the at least one track support platform **1805** may be supported on a pillar **1820** on the ground **1835**. With this exemplary embodiment, two track support platforms **1805** and an upper support **1825** are secured to the pillar **1820**. As shown in FIG. **18**, a plurality of pillar supports **1850** may be attached to the pillar **1820** and structured and arranged to support one or more of the two track support platforms **1805** and/or the upper support **1825** (not shown).

[0120] In accordance with aspects of the disclosure, as shown in FIG. **18**, at least one sheet of flexible material **1830** (or a membrane) is attached between the track support platforms **1805** and the pillar **1820** to create an enclosed environment **1845**. The flexible material **1830** is held in tension between the track support platforms **1805** and the pillar **1820**.

[0121] FIGS. **19A-19B** illustrate schematic views of a portion of an exemplary low-pressure environment support structure in accordance with embodiments of the present disclosure. In embodiments, support wires may be used to additionally support the flexible material. As shown with the arrangement **1900** in FIG. **19A**, a support structure **1905** (e.g., a track support platform, an angled support, a support pillar, support ring, a box girder structure, and/or attachment structure) for forming an enclosed environment includes channels **1910** structured and arranged to accommodate respective support wires **1915**. In accordance with aspects of the disclosure, a flexible material **1920** is arranged around the support structure **1905** and the support wires **1915** to form one or more enclosed environments **1930**. As shown with the arrangement **1900**, by utilizing the channels **1910**, the flexible material **1920** may be more evenly supported by the support structure **1905** and the support wires **1915**, which may prevent or reduce wrinkles and/or uneven stresses on the flexible material **1920**. In embodiments, the spacing of the channels **1910** and the size of the channels **1910** may be modified, for example, depending on the size and type of support wires **1915** used.

[0122] As shown with the arrangement **1950** in FIG. **19B**, a support structure **1955** (e.g., a track support platform, an angled support, a support pillar, support ring, a box girder structure, and/or attachment structure) for forming enclosed environment has support wires **1915** arranged on the surface thereof. In accordance with aspects of the disclosure, a flexible material **1970** is arranged around the support structure **1955** and the support wires **1915** to form one or more enclosed environments **1930** (as schematically indicated). As shown with the arrangement **1950**, the flexible material **1970** may wrap approximately around the support wires **1915**.

[0123] FIGS. **20A-20B** illustrate schematic views of a portion of an exemplary low-pressure environment support structure **2000** in accordance with embodiments of the present disclosure. As shown in FIG. **20A**, a wire support structure **2025** having channels **2010** structured and arranged to accommodate respective support wires **1915** may be arranged on a support structure **2005** (e.g., a track support platform, an angled support, a support pillar, support ring, a box girder structure, and/or attachment structure) for forming an enclosed environment. In accordance with aspects of the disclosure, a flexible material **2020** is arranged around the wire support structure **2025**, the support structure **2005** and the support wires **1915** to form one or more enclosed environments. As shown with the arrangement **2000**, by utilizing the wire support structure **2025** the bending induced in the sup-

port wires **1915** and/or the flexible material **2020** may be reduced. As the radius around which support wires **1915** and/or the flexible material **2020** decreases, the ability for the material to endure the tensile forces decreases. As such, by increasing the radius of the bend using the wire support structure **2025**, the ability for the materials (e.g., support wires **1915** and/or flexible material **2020**) to endure the tensile forces may be increased. Furthermore, by increasing the surface contact of the support wires **1915** as they bend around the support structure **2005**, wear on the support wires can be reduced. As shown in FIG. **20B**, in some embodiments, the flexible material **2020** may include one or more reinforcement regions **2030**, for example arranged in proximity to the bend, which are configured to have greater strength and/or resistance to tear, for example.

[0124] FIG. **21** illustrates a schematic view of an exemplary low-pressure environment connector structure in accordance with embodiments of the present disclosure. As shown in FIG. **21**, a flexible material **2110** may include a plurality of attachment beads **2115** (or rods, for example) along a periphery thereof or through a central portion thereof. The attachment beads **2115** (or rods) are structured, arranged, and configured to cooperatively engage with a corresponding slot **2125** (or groove) in an attachment structure **2105**. As shown in FIG. **21**, a sealing flap **2120** may be flexibly (pivotally) mounted to the attachment structure **2105** and configured to press against the flexible material **2110** to form a seal therewith. In embodiments, the sealing flap **2120** may be mounted in a flexed manner to provide a sealing force. In additional embodiments, the sealing flap **2120** may include an adhesive or other suitable securing material to enhance the seal provided between the sealing flap **2120** and the flexible material **2110**.

[0125] Another embodiment of the present disclosure may be used to create a junction or track switching location. For example, rather than centering around one vacuum transportation corridor, the system can take on numerous shapes to center around a large area of land or water. The tension members then support the membrane similar to a tent, allow for the intersection of tubes within the confines of the low-pressure environment.

[0126] Although the present specification describes components and functions that may be implemented in particular embodiments with reference to particular standards and protocols, the disclosure is not limited to such standards and protocols. Such standards are periodically superseded by faster or more efficient equivalents having essentially the same functions. Accordingly, replacement standards and protocols having the same or similar functions are considered equivalents thereof.

[0127] The illustrations of the embodiments described herein are intended to provide a general understanding of the various embodiments. The illustrations are not intended to serve as a complete description of all of the elements and features of apparatus and systems that utilize the structures or methods described herein. Many other embodiments may be apparent to those of skill in the art upon reviewing the disclosure. Other embodiments may be utilized and derived from the disclosure, such that structural and logical substitutions and changes may be made without departing from the scope of the disclosure. For example, while many of the structures discussed herein may be used in the context of a low-pressure environment for a high-speed transportation system, the enclosed environments may also be utilized in different con-

texts (e.g., vacuum facilities for clean rooms). Additionally, the illustrations are merely representational and may not be drawn to scale. Certain proportions within the illustrations may be exaggerated, while other proportions may be minimized. Accordingly, the disclosure and the figures are to be regarded as illustrative rather than restrictive.

**[0128]** Accordingly, the present disclosure provides various systems, structures, methods, and apparatuses. Although the disclosure has been described with reference to several exemplary embodiments, it is understood that the words that have been used are words of description and illustration, rather than words of limitation. Changes may be made within the purview of the appended claims, as presently stated and as amended, without departing from the scope and spirit of the disclosure in its aspects. Although the disclosure has been described with reference to particular materials and embodiments, embodiments of the invention are not intended to be limited to the particulars disclosed; rather the invention extends to all functionally equivalent structures, methods, and uses such as are within the scope of the appended claims.

**[0129]** One or more embodiments of the disclosure may be referred to herein, individually and/or collectively, by the term “invention” merely for convenience and without intending to voluntarily limit the scope of this application to any particular invention or inventive concept. Moreover, although specific embodiments have been illustrated and described herein, it should be appreciated that any subsequent arrangement designed to achieve the same or similar purpose may be substituted for the specific embodiments shown. This disclosure is intended to cover any and all subsequent adaptations or variations of various embodiments. Combinations of the above embodiments, and other embodiments not specifically described herein, will be apparent to those of skill in the art upon reviewing the description.

**[0130]** The Abstract of the Disclosure is provided to comply with 37 C.F.R. §1.72(b) and is submitted with the understanding that it will not be used to interpret or limit the scope or meaning of the claims. In addition, in the foregoing Detailed Description, various features may be grouped together or described in a single embodiment for the purpose of streamlining the disclosure. This disclosure is not to be interpreted as reflecting an intention that the claimed embodiments require more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive subject matter may be directed to less than all of the features of any of the disclosed embodiments. Thus, the following claims are incorporated into the Detailed Description, with each claim standing on its own as defining separately claimed subject matter.

**[0131]** The above disclosed subject matter is to be considered illustrative, and not restrictive, and the appended claims are intended to cover all such modifications, enhancements, and other embodiments which fall within the true spirit and scope of the present disclosure. Thus, to the maximum extent allowed by law, the scope of the present disclosure is to be determined by the broadest permissible interpretation of the following claims and their equivalents, and shall not be restricted or limited by the foregoing detailed description.

**[0132]** Accordingly, the novel architecture is intended to embrace all such alterations, modifications and variations that fall within the spirit and scope of the appended claims. Furthermore, to the extent that the term “includes” is used in either the detailed description or the claims, such term is intended to be inclusive in a manner similar to the term

“comprising” as “comprising” is interpreted when employed as a transitional word in a claim.

**[0133]** While the invention has been described with reference to specific embodiments, those skilled in the art will understand that various changes may be made and equivalents may be substituted for elements thereof without departing from the true spirit and scope of the invention. While exemplary embodiments are described above, it is not intended that these embodiments describe all possible forms of the invention. Rather, the words used in the specification are words of description rather than limitation, and it is understood that various changes may be made without departing from the spirit and scope of the disclosure. In addition, modifications may be made without departing from the essential teachings of the invention. Furthermore, the features of various implementing embodiments may be combined to form further embodiments of the invention.

What is claimed is:

1. A high-speed transportation system, the system comprising:

at least one enclosed volume that is configured to be maintained as a low-pressure environment;

at least one track along a transportation path within the at least enclosed volume; and

a plurality of capsules configured for travel through the at least one enclosed volume between stations,

wherein the at least one enclosed volume is at least partially defined by at least one flexible material structured and arranged to withstand a tensile load.

2. The high-speed transportation system of claim 1, further comprising at least one support structure configured to support the flexible material and structured and arranged to withstand a compressive load.

3. The high-speed transportation system of claim 1, wherein the system additionally comprises at least one track support platform.

4. The high-speed transportation system of claim 1, wherein the at least one flexible material together with the at least one track support platform defines the at least one enclosed volume.

5. The high-speed transportation system of claim 1, wherein the flexible material defines the at least one enclosed volume.

6. The high-speed transportation system of claim 2, wherein the at least one support structure comprises at least one vertical support.

7. The high-speed transportation system of claim 6, wherein the at least one flexible material together with the at least one vertical support defines the at least one enclosed volume.

8. The high-speed transportation system of claim 2, wherein the at least one support structure comprises a plurality of support structures spaced along the transportation path.

9. The high-speed transportation system of claim 2, wherein the at least one support structure comprises at least one angled support.

10. The high-speed transportation system of claim 9, wherein the at least one angled support is attached to a track support platform.

11. The high-speed transportation system of claim 9, wherein the at least one angled support is attached to at least one vertical support.

12. The high-speed transportation system of claim 9, wherein the at least one angled support extends in a downwardly direction.

13. The high-speed transportation system of claim 9, wherein the at least one angled support extends in an upwardly direction.

14. The high-speed transportation system of claim 2, wherein the at least one support structure comprises an arch structure.

15. The high-speed transportation system of claim 2, further comprising a second flexible material structured and arranged to define a second enclosed volume that encloses the first enclosed volume, and which is configured to be maintained at a pressure higher than a pressure outside of the second enclosed volume.

16. The high-speed transportation system of claim 15, wherein the second enclosed volume is arranged in an underwater environment.

17. The high-speed transportation system of claim 1, further comprising at least one guideway or walkway arranged within the at least one enclosed volume.

18. The high-speed transportation system of claim 2, wherein the at least one support structure comprises a plurality of support rings, and the system additionally comprises a plurality of support wires connected between two of the plurality of support rings, wherein the at least one flexible material is at least supported by the plurality of support wires.

19. The high-speed transportation system of claim 18, wherein the plurality of support wires between adjacent support rings are configured with a 90° clocking.

20. The high-speed transportation system of claim 18, wherein the support wires comprise at least one of: steel, fibers, polymer materials, webbing, and filaments.

21. The high-speed transportation system of claim 1, wherein the tensile load is due at least in part to a pressure

differential between the low-pressure environment of the enclosed volume, and an ambient pressure outside the enclosed volume.

22. The high-speed transportation system of claim 1, wherein the at least one flexible material comprises at least one of:

- a plastic membrane;
- a plastic membrane having embedded filaments;
- a layer of metal;
- a translucent material; and
- a transparent material.

23. The high-speed transportation system of claim 1, wherein the at least one flexible material is impermeable to air.

24. The high-speed transportation system of claim 1, further comprising:

- a propulsion system adapted to propel the at least one capsule through the enclosed volume; and
- a levitation system adapted to levitate the capsule within the enclosed volume.

25. A structure, comprising:

- at least one flexible material structured and arranged to withstand a tensile load;
- at least one support structure configured to support the flexible material and structured and arranged to withstand a compressive load; and
- at least one enclosed volume at least partially defined by the at least one flexible material, the enclosed at least one volume being configured to be maintained as a low-pressure environment for a high-speed transportation system.

26. The structure of claim 25, further comprising at least one track along a transportation path within the at least enclosed volume, wherein the at least one track is configured for supporting a capsule configured for travel through the at least enclosed volume.
